**Objective:** Previous studies found that low vitamin D levels were modestly associated with risk of stroke and poor functional outcome after stroke. In addition, vitamin D deficiency has been linked with cognitive decline. Our study aimed to explore the potential relationship between vitamin D levels in the short-term acute phase of ischemic stroke and cognitive impairment at 1 month.

**Methods:** In total, 354 ischemic stroke patients were consecutively enrolled in the study and received 1-month follow-up. The serum levels of vitamin D were measured within 24 hours after admission. Cognitive function was evaluated by the Mini-Mental State Examination (MMSE) at 1 month after acute ischemic stroke. Cognitive impairment was defined according to different education levels.

**Results:** According to MMSE scores, 114 participants (32.2%) had cognitive impairment at 1 month. Patients with vitamin D deficiency were more likely to have cognitive impairment than those with vitamin D insufficiency and vitamin D sufficiency ( $P < 0.001$ ). After adjusting for potential confounders in our Cox proportional hazards model, vitamin D deficiency was independently associated with the development of cognitive impairment in acute ischemic stroke patients.

**Conclusion:** Independent of established risk factors, vitamin D deficiency in the short-term phase of ischemic stroke was associated with a higher incidence of 1-month cognitive impairment.

**Keywords:** vitamin D, cognitive impairment, ischemic stroke, Mini-Mental State Examination

## Introduction

Cognitive impairment is a common and important complication after stroke, with prevalence ranging widely from 10% to 82%.<sup>1</sup> The presence of poststroke cognitive impairment (PSCI) has been associated with poor functional outcome,<sup>2</sup> reduced quality of life,<sup>3</sup> higher risk of recurrent stroke<sup>4</sup> and aggravated economic burden.<sup>5</sup> However, multiple factors have been found to lead to the progression of PSCI, including older age, family history, sex difference and poor educational status,<sup>6</sup> which are not readily amenable to prevention and treatment. Therefore, it is necessary to find novel risk factors that may improve the prediction and early diagnosis of PSCI.

Vitamin D is a unique neurosteroid hormone necessary for maintaining musculo-skeletal health; its deficiency is associated with many conditions including obesity, hypertension, diabetes mellitus, cardiovascular diseases (CVDs) and dementia.<sup>7-9</sup> Accumulating evidence suggests that the vitamin D receptor (VDR) and the enzyme required for vitamin D activation have been found in areas of the brain essential for cognition.<sup>10</sup>

More recently, several experimental studies have suggested that vitamin D deficiency could mediate neurodegenerative processes involved in Alzheimer's disease (AD).<sup>11,12</sup> Furthermore, previous studies found that low vitamin D levels were associated with increased odds of cognitive dysfunction in the elderly and in people with dementia.<sup>13–17</sup> It is also reported that vitamin D deficiency is common in patients after stroke and is associated with poor functional outcome.<sup>18–21</sup> A cross-sectional study conducted in the rehabilitation period of stroke found a positive association between vitamin D levels and cognitive function.<sup>22</sup> However, to date, as we know, this is the first prospective study to explore the relationship between vitamin D levels in the acute period of stroke and the development of cognitive impairment at 1 month.

In this study, we measured the serum levels of vitamin D within 24 hours after admission in patients with acute ischemic stroke and investigated the relationship of vitamin D levels with the incidence of cognitive impairment at 1 month.

## Materials and methods

### Subjects

The study obtained the approval of the ethics committee of the First Affiliated Hospital of Wenzhou Medical University in compliance with the Declaration of Helsinki. All participants or their relatives provided written informed consents. Patients who had suffered a stroke and were admitted to the Stroke Unit of the First Affiliated Hospital of Wenzhou Medical University within 7 days were included in this study from October 2013 to February 2015. The inclusion criteria were as follows: 1) age between 18 and 80 years; 2) first-ever acute stroke occurring within 7 days after stroke onset; 3) diagnosed with computerized tomography (CT) or magnetic resonance imaging (MRI) at the time of admission. The exclusion criteria were as follows: 1) primary hemorrhagic stroke or transient ischemic attack; 2) patients with any central nervous system disease such as pre-stroke dementia or severe cognitive impairment, Parkinson's disease; 3) severe aphasia or dysarthria, visual or auditory impairment and acute or chronic inflammatory disease; 4) patients taking vitamin D and/or calcium supplementation before stroke onset.

### Clinical measurements

Demographic data included age, gender and years of education. Behavioral risk factors included body mass index (BMI), current smoking and drinking alcohol. Clinical variables included history of hypertension, diabetes mellitus, coronary artery disease (CAD), hyperlipidemia, stroke etiology as well as the serum levels of vitamin D. Stroke severity was assessed using the National Institutes of Health Stroke Scale (NIHSS)

within 24 hours of admission. Functional outcomes were evaluated by the Barthel Index (BI) at discharge. CT or MRI was performed on patients within 72 hours after admission. The lesion locations of acute stroke were recorded.

### Psychological measurement

Cognitive function was assessed by trained neurologists who were blinded to the subjects' clinical presentations and laboratories using the Chinese version of the Mini-Mental State Examination (MMSE) at 1 month poststroke. The MMSE has been translated into Chinese and validated for reliability and validity as a screening tool for cognitive impairment in the Chinese population. Lower scores indicate greater cognitive impairment, and cognitive impairment was defined by an MMSE score  $\leq 19$  points (illiterate),  $\leq 22$  points (education level of primary school), or  $\leq 26$  points (education level of secondary school or above).<sup>23</sup>

### Laboratory tests

Blood samples were obtained within 24 hours of hospital admission. Vitamin D status was measured by blood 25-hydroxyvitamin D [25(OH)D], the main active form of vitamin D and a good indicator of the whole level of vitamin D. Serum 25(OH)D levels were measured through a competitive protein binding assay at our hospital's laboratory. In both cohorts, serum 25(OH)D concentrations were divided into clinically relevant categories, vitamin D deficiency ( $< 25$  nmol/L), vitamin D insufficiency ( $\geq 25$  to  $< 50$  nmol/L) and vitamin D sufficiency ( $\geq 50$  nmol/L).<sup>24</sup>

### Statistical analyses

Continuous variables were shown as mean (SD) or medians (quartiles) depending on the normal or non-normal distribution of data, while categorical variables were represented as percentages. Student's *t*-test was applied for normal distribution test, while the asymmetrically distributed variables were compared using the Mann–Whitney *U*-test, and chi-squared test was employed for proportions. In addition, Cox proportional hazards model was employed to analyze and determine the independent risk factors of PSCI, which allows adjustment for potential confounding factors. All statistical analyses were performed with SPSS for Windows, version 23.0 (SPSS Inc., Chicago, IL). A *P*-value  $< 0.05$  was considered statistically significant.

## Results

### Baseline characteristics

A total of 634 individuals were enrolled in the study and 410 patients were eligible for the study. Consequently,

354 patients completed the follow-up and were included in this study (Figure 1). Among 354 patients, the mean age was  $62.51 \pm 10.12$  years, and 37.3% were females; the median serum vitamin D concentration was 49.58 nmol/mL (IQR, 31.95–65.09 nmol/mL). Table 1 shows the basic characteristics of patients with and without PSCI. Among the study population, 114 (32.2%) patients were diagnosed with PSCI at 1-month follow-up. Compared with non-PSCI patients, PSCI patients were more likely to be older, female and have higher NIHSS scores, lower BI scores and lower education level. Meanwhile, less cigarette smokers and alcohol drinkers were found in subjects with PSCI.

### Association between serum level of vitamin D and cognitive impairment

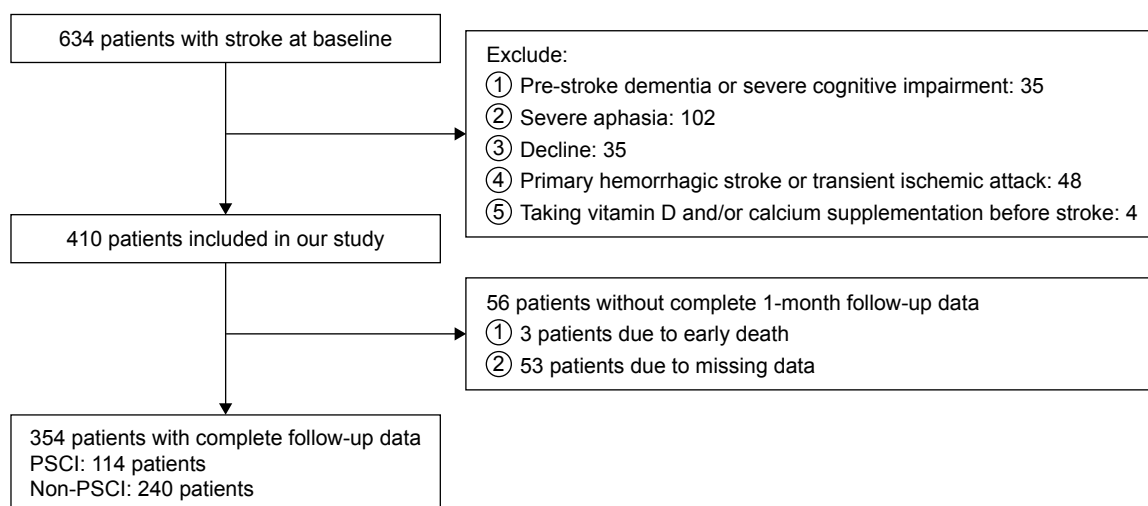

Median (IQR) values of vitamin D in non-PSCI patients and PSCI patients were 51.64 (36.39–66.32) and 41.47 (19.24–57.10), respectively. Compared to those without PSCI, lower vitamin D levels were found in subjects with PSCI ( $P < 0.001$ ). In addition, there were significant differences observed between the PSCI and non-PSCI patients according to different vitamin D status. Indeed, the incidence of vitamin D deficiency ( $< 25$  nmol/L) was significantly higher in the PSCI group ( $P < 0.001$ ), whereas it was significantly lower in the PSCI group ( $P = 0.015$ ). Moreover, Figure 2 shows a significant intergroup difference in the incidence of PSCI ( $P < 0.001$ ). Patients with vitamin D deficiency were more likely to have cognitive impairment than those with vitamin D insufficiency and vitamin D sufficiency (58.3% vs 28.1%, 26.0%,  $P < 0.001$ ) (Figure 2).

Table 2 shows the Cox proportional hazards model for the association between vitamin D status and cognitive impairment. For the whole data of stroke patients, vitamin D sufficiency was taken as a reference and the presence of PSCI taken as a dependent variable for vitamin D values; after adjusting for potential confounders, vitamin D deficiency ( $< 25.0$  nmol/L) was independently associated with the prevalence of PSCI (RR 2.124, 95% CI 1.307–3.449,  $P = 0.002$ ). Moreover, years of education was significantly associated with the development of PSCI in acute ischemic stroke patients (RR 0.940, 95% CI 0.884–0.999,  $P = 0.047$ ; Table 2).

### Discussion

To the best of our knowledge, this is the first study to investigate the prospective relationship between vitamin D levels and PSCI. In our study, the main finding was that vitamin D deficiency was associated with a higher incidence of cognitive impairment in patients with acute ischemic stroke. The association remained significant after adjusting for potential confounders listed in Table 2.

In the present study, 32.2% of patients with acute ischemic stroke were diagnosed with PSCI at 1 month, which is consistent with previous findings.<sup>25–27</sup> Additionally, some studies demonstrated that education is an important factor that affects cognitive function.<sup>28,29</sup> Previous studies have discovered that education had the most potent effect on MMSE performance, which would influence individuals' capability of comprehension and execution, or might reflect the innate intelligence status that inhibited the subjects to complete higher levels of education.<sup>30</sup> Our study found that education has a protective effect to cognitive function, which was consistent with previous studies.<sup>31</sup> The addition of serum

vitamin D to a conventional risk factor model could increase risk prediction for PSCI.

In accordance with the present results, a growing number of studies have already reported lower vitamin D levels with cognitive impairment or dementia.<sup>13–17</sup> As far as we know, studies investigating the possible relationship between vitamin D levels and the development of cognitive impairment with acute ischemic stroke were rare. In a cross-sectional study conducted in Turkey, vitamin D levels were associated with cognitive impairment in stroke patients in rehabilitation period.<sup>22</sup> It was a study of small sample size and could not clarify the prospective relationship between vitamin D and PSCI. On that basis, we carried out the relevant study, and our research showed that vitamin D deficiency increased the risk of PSCI by 2.124-fold at 1-month follow-up, suggesting that the serum vitamin D might be a potential predictive marker for PSCI.

The mechanisms by which serum vitamin D affects cognitive function after ischemic stroke remain unclear, and

growing evidence suggests that vitamin D plays an important role in brain health and function.<sup>17</sup> Vitamin D exerts various effects on brain through VDR and the vitamin D activating enzyme 1 $\alpha$ -hydroxylase, which are broadly present in both neurons and glial cells in many areas of human brain critical for cognition.<sup>32,33</sup> Vitamin D is involved in preventing neurodegeneration through several pathways including antioxidative mechanisms, modulation of immune response, regulation of calcium homeostasis, inhibition of pro-inflammatory agents and detoxification.<sup>10,12,34,35</sup> Calcitriol (1, 25-(OH) 2D3) is the active metabolite of vitamin D3 and attenuates the production of nitric oxide through inhibiting the expression of inducible nitric oxide synthase in the spinal cord and brain.<sup>36</sup> High nitric oxide levels are deemed to participate in inflammatory disorders, neurodegenerative disorders and neurotoxicity.<sup>37</sup> Besides, low vitamin D levels are known to affect macrophage and lymphocyte activity in atherosclerotic plaques and to facilitate chronic inflammation in the artery wall.<sup>38</sup> Atherosclerosis and inflammatory reaction of artery wall play a pivotal role in the occurrence of cognitive impairment.<sup>27</sup> It is known that vitamin D is inversely associated with increased cardiovascular (CV) risk itself and CV risk factors, which are known risk factors for cognitive impairment and dementia, including arterial hypertension, endothelial dysfunction and atherosclerosis.<sup>39</sup> In addition, vitamin D stimulates neurogenesis and upregulates the synthesis of several neurotrophin factors important for the survival, development and functioning of neurons.<sup>40,41</sup> Vitamin D is considered to be involved in neurophysiology at the level of gene transcription, in regulating multiple neurotransmitters, including acetylcholine and dopamine.<sup>32,42</sup> As a result, in the case of severe hypovitaminosis D, a reduction of nerve conduction velocity has been observed.<sup>43</sup> Therefore, the findings mentioned above indicate that vitamin D may play a critical role in the development of PSCI.

However, our study has several limitations. First, patients with aphasia or a serious condition were excluded, as well as patients who failed to measure serum levels of vitamin D, which might lead to an underestimation of the actual incidence of PSCI. Second, serum vitamin D was measured only once (within first 24 hours after admission), and it is necessary to conduct a further longitudinal study assessing how vitamin D levels change over time after stroke to provide better prognostic information. Third, the variable years of education might impose some bias on the results. In future studies, we should control the years of studies interval and focus more on women when defining the inclusion criteria. Fourth, malnutrition, which could have an influence of vitamin D levels, is a risk factor for poor outcomes in patients with acute ischemic stroke.<sup>44</sup> Our study did not collect information on nutritional status, which may influence the results. Lastly, the information of medications during hospitalization was not recorded.

## Conclusion

In summary, in spite of these limitations, our study demonstrates an important relationship between serum levels of vitamin D within 24 hours after admission and the development of PSCI at 1 month after stroke. Further prospective studies and randomized clinical trials are critical in examining whether supplements of vitamin D offer a potential prevention or therapeutic target for PSCI.

### Clinical Interventions in Aging

## Publish your work in this journal

Clinical Interventions in Aging is an international, peer-reviewed journal focusing on evidence-based reports on the value or lack thereof of treatments intended to prevent or delay the onset of maladaptive correlates of aging in human beings. This journal is indexed on PubMed Central, MedLine,

CAS, Scopus and the Elsevier Bibliographic databases. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.

Submit your manuscript here: <http://www.dovepress.com/clinical-interventions-in-aging-journal>
