# High prevalence of vitamin D deficiency among the South Asian adults: a systematic review and meta-analysis

Mahbubul H. Siddiquee<sup>1,2\*†</sup>, Badhan Bhattacharjee<sup>1,2†</sup>, Umme Ruman Siddiqi<sup>3</sup> and Mohammad MeshbahurRahman<sup>4</sup>

## Abstract

**Background:** Vitamin-D deficiency is linked to a wide range of chronic and infectious diseases. Body of literature suggested that the prevalence of this deficiency can have geographical variation. Although vitamin D deficiency is frequently reported in the South Asian population, the scarcity of systematic reviews and meta-analysis means the true extent of the disease and the underlying factors causing it are poorly characterized.

**Methods:** A systematic search was performed using two databases (PubMed and Scopus) and one search engine (Google Scholar) for original studies on the South Asian population (published from January 1, 2001, to December 31, 2019). Following the search, a random effect meta-analysis was performed to calculate population-level weighted average, the pooled prevalence of deficiency, and heterogeneity of vitamin D among different countries and genders; in addition to South Asia as a whole.

**Results:** Our study, based on our selection criteria was narrowed down to a total of 44,717 participants; which spanned over 65 studies from five South Asian countries. Overall, the pooled prevalence of deficiency was 68% [95% CI: 64 to 72%] with significant heterogeneity ( $I^2 = 98\%$ ;  $p = 0.00$ ). The average level of vitamin D ranged from 4.7 to 32 ng/mL, with a weighted mean of 19.15 ng/mL (weighted standard deviation 11.59 ng/mL). The highest prevalence of vitamin D deficiency was found in Pakistan (73%; 95% CI: 63 to 83%) followed by Bangladesh (67%; 95% CI: 50 to 83%), India (67%; 95% CI: 61 to 73%), Nepal (57%; 95% CI: 53 to 60%) and Sri Lanka (48%; 95% CI: 41 to 55%), respectively. This finding indicated a high degree of heterogeneity among the population. ( $I^2 = 98.76\%$ ), Furthermore, a gender-wise analysis suggested that in South Asia, the prevalence of vitamin D deficiency was higher in females than males.

**Conclusion:** Our findings reveal highly prevalent and variable vitamin D deficiency among the adults of different South Asian countries. Findings from this review would be helpful to generate hypotheses and explore the factors affecting the inter-country variability, alongside strengthening evidence for governments to prioritize mitigation strategies in this region.

**Keywords:** Vitamin D deficiency, South Asia, Adults, Systematic review

## Background

The critical roles of vitamin D in several endocrine, paracrine, and autocrine activities have been specified in various studies [1–3]. Vitamin D deficiency in adults acts as a key factor for the development of various communicable and non-communicable diseases. For instance, inadequate levels of vitamin D play a major role for the development of diseases like colon cancer, breast cancer, cardiovascular diseases, diabetes mellitus, multiple sclerosis, rheumatoid arthritis, Parkinson's disease, tuberculosis etc. [1–4]. Despite the high physiological importance, deficiency of this vitamin is commonly reported around the world.

Study reports suggest that approximately 1 billion people worldwide are affected with vitamin-D deficiency and around 50% of the global population have vitamin D insufficiency [1, 3]. According to literature, the prevalence of vitamin D deficiency in Europe, USA and Middle East has been reported to range from 20 to 90% [5, 6]. Similar trends have been reported in countries like Australia, India, Africa, South America, Turkey and Lebanon [1, 3, 5, 6]. These reports suggest that insufficient vitamin D is a problem for both developing and developed countries.

Alongside high prevalence, a wide variation of vitamin D status exists among different countries. For example, study reports showed that adult population in the Middle Eastern countries such as Iran and Syria have very low average level of vitamin D (14 ng/mL and 10 ng/mL, respectively) [7, 8], compared to the adults in the European countries like Denmark and France (26 ng/mL and 24 ng/mL, respectively) [9, 10].

A number of factors have been highlighted as underlying variables to explain this world-wide variation of vitamin D status among different populations. Degree of sunlight exposure and the factors that influence its duration and intensity ultimately influence the level of vitamin D in any population [1–3]. Among such factors, geographical location is key [11]. However, alongside sunlight exposure, skin color, age, comorbidities are also reported as modulating factors to explain variations of vitamin D levels, among populations [1–3, 11]. Therefore, understanding the comparative variability and diversity of prevailing factors that may influence levels of vitamin D among populations, is imperative from a public health standpoint.

South Asia (SA) occupies eight nations and these nations are Bangladesh, India, Pakistan, Nepal, Bhutan, Maldives, Sri Lanka and Afghanistan. These eight nations have a total population of around 1.8 billion, representing over 24% of the total world population [12, 13]. Although, the individual SA countries share some common ethnic and cultural characteristics, differences are observed for language, religion clothing practice, food habit etc. [14, 15].

Communicable and non-communicable diseases, nearly all of which are associated with vitamin D deficiency, are highly prevalent among the SA population [16–18]. Despite the possibility of vitamin D being a potential risk factor, we found only one systematic review on the adult population (Indian population only yet on quantitative measurement of serum vitamin D concentration, not percentage prevalence of deficiency) [19]. Thus, a huge knowledge gap exists about the true extent of vitamin D deficiency in different SA countries. This systematic review intends to address this knowledge gap through the performance of a meta-analysis.

## Methods

We followed the preferred method of reporting items for systematic reviews and meta-analyses (PRISMA-P 15) guidelines, for conducting this systematic review [20].

### Data source and search strategy

Two main databases (PubMed and Scopus) and one search engines (Google Scholar) were systematically explored for original articles on vitamin D deficiency of SA adult population (After signing out of all Google accounts, a search was performed to avoid personalized results). The search was done independently by two researchers (BB and MMR) (from October 12, 2019 to January 12, 2020) to find out the studies conducted from 2001 until the search date. The details of the search strategy, list of original MeSH terms and the alternative terms (to minimize chance of exclusion) used in this study is provided in the additional file (Table- A1).

To maximize the search efficiency, corresponding authors profiles (on Google Scholar, Research Gate, Orchid, and in current organizations) and reference list of our selected studies were also explored. To ensure the inclusion of grey literature in this review, we went through online archives of newspapers which are published in English language among SA countries such as Times of India, The Daily star, Dawn, Daily Bhutan, Maldives insider, The Himalayan times, Daily Mirror etc. Government reports and published abstracts (in electronic version) from conferences held in the SA countries were also explored as relevant sources.

### Eligibility criteria

In this study, vitamin D deficiency was defined as per the definition proposed by the Clinical Practice Guideline of the Endocrine Society (that recommends < 20 ng/mL as cut off) [21] Studies were selected if they reported vitamin D deficiency of SA adults. The inclusion criteria were- 1) study subjects aged 18 years or above; 2) original peer reviewed observational studies (cross-sectional, longitudinal, case-control (control groups only),

randomized clinical trial (baseline/placebo groups only); 3) study conducted on community level or in hospital settings on apparently healthy population (people with minor illness whose physical condition were not correlated with any chronic disease); 4) study conducted in SA countries (Bangladesh, India, Pakistan, Nepal, Bhutan, Maldives, Sri Lanka and Afghanistan); 5) and, study conducted from January 1st, 2001 to December 31st, 2019.

The following exclusion criteria were applied- 1) studies (or groups) that had sample size less than 50 [22]; 2) reported vitamin D levels after some form of intervention or supplementation; 3) conducted on groups other than healthy adults (pregnant women, infants, neonates and adolescents); 4) reported prevalence of vitamin D deficiency associated to any kind of disease (chronic kidney, liver and heart disease, cancer, diarrhea, anemia, diabetes) or disease related to any coexisting morbidity (body aches and pain, proximal muscle weakness, osteoporosis); 5) conducted on special group of population such as short stature or mentally retarded; 6) did not report prevalence of vitamin D deficiency and mean level of vitamin D status; 7) studies which met selection criteria but the full text could not be retrieved from the authors after requests.

Mendeley Desktop software (version 1.19.4) was used to manage the references and duplications. After checking duplications, papers were independently verified by two researchers (MHS and URS) before final inclusion in meta-analysis. Disagreements were resolved through discussion with co-authors.

#### Data extraction

A standardized data table was used to extract data from all eligible studies. For each study, the following information was extracted: publication details [e.g., first author, publication date, journal name, and publisher]; research setting (community-based or hospital-based); population and study design [e.g., country, study area and sample size]; participants' characteristics and major findings [e.g., gender, socio-economic status, method of measurements, mean level of vitamin D and prevalence percentage of deficiency]. All investigators had checked the accuracy of the data extracted through multiple revisits to the included articles.

In our selected studies, where mean values of 25(OH) D were given in nanomol per unit liter (nmol/L), we converted to nanogram per milliliter (ng/mL) by dividing with 2.5 (according to the international unit conversion system) to maintain the uniformity. Since the study's outcome of interest included the prevalence of vitamin D deficiency in SA countries, vitamin D prevalence and mean value was only extracted after reading the selected papers in full.

#### Evaluation of study quality

The risk of bias for each selected study were assessed by Badhan using Hoy et al. [23] guidelines on conducting prevalence and incidence reviews. If the studies full-fill any criteria with a score of 0 it implies a low risk of bias, and if studies full fill a criteria with score of 1 this indicates a high risk of bias. Risk of bias was assessed for all original articles.

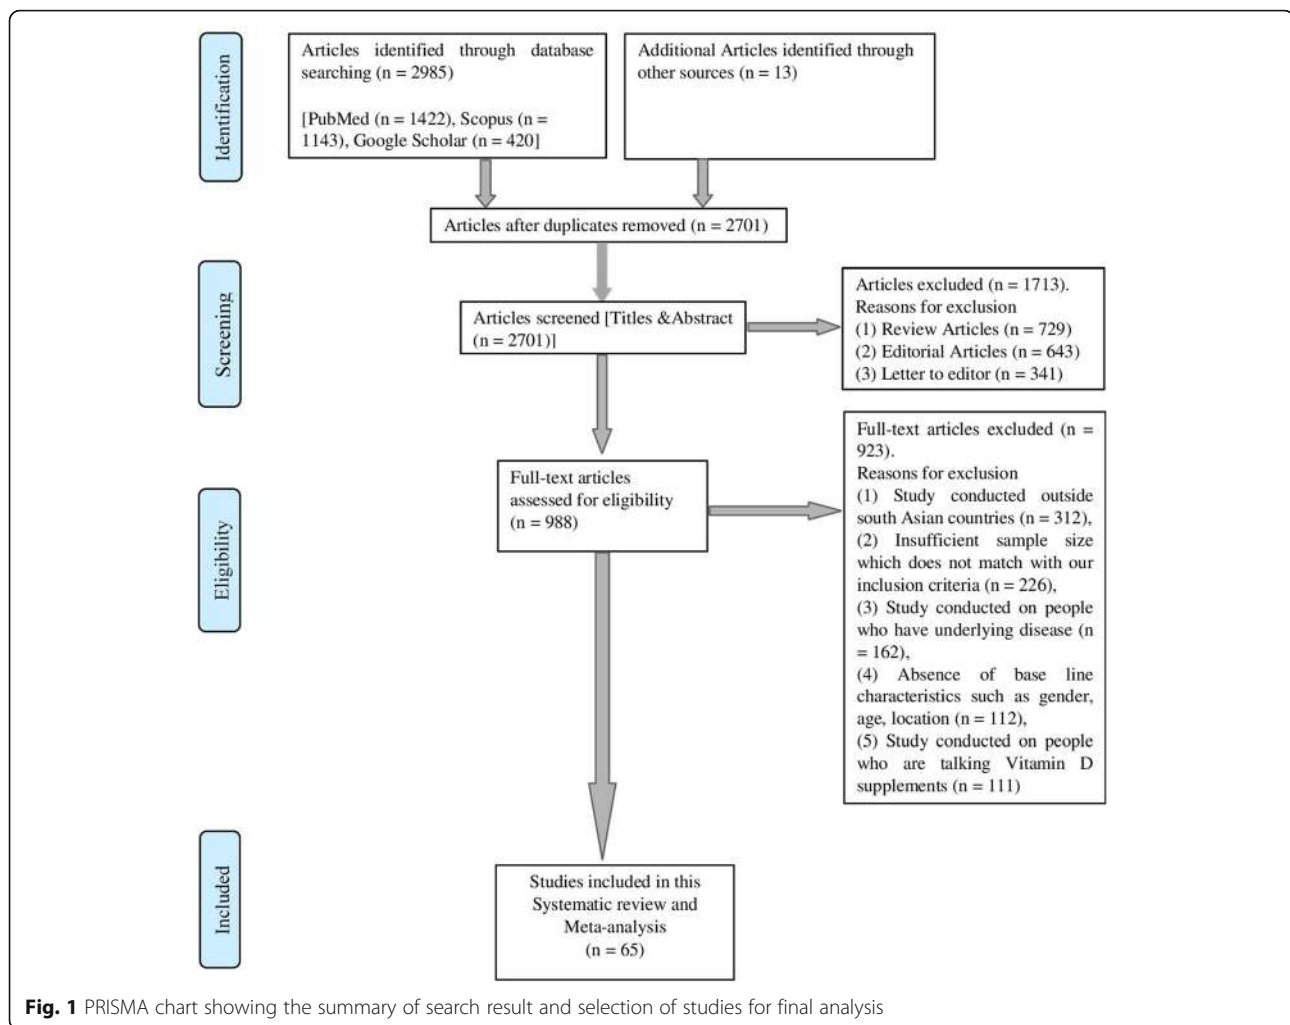

#### Statistical analysis

Mean value of participant's vitamin D status and prevalence of vitamin D deficiency in SA countries were considered as summary measurements. According to literature, serum level of vitamin D may depend on a number of confounding variables (e.g., geolocation, gender, age, socioeconomic status, clothing practices, skin complexion, etc.) and their effects are likely to vary among different populations [1–3, 11]. Since the individual studies included in our final data set did not report the effects of all these variables, we used random-effect model to obtain pooled prevalence with a 95% confidence interval [24–26]. Country-wise and gender-wise analysis was also performed according to the vitamin D deficient participants. Heterogeneity was assessed using Cochran's Q test and the  $I^2$  statistics. Substantial heterogeneity was indicated with an  $I^2$  of more than 75% [27]. Publication bias and small study effects were also examined using funnel plot and Egger's test. All statistical analyses were conducted by Stata version 15 (Stata Corp, College Station, TX) using the 'metaprop', 'metabias', 'metafunnel' commands. Weighted mean level of serum vitamin D was calculated in Microsoft Excel (version; 2016).

#### Results

Our systematic search retrieved 2998 study articles from different databases by using the search strategy elaborated earlier. Among these 2998 articles, 2933 were excluded because of being unable to fully fill our inclusion criteria. Finally, 65 study articles were selected. Study article selection process is shown in (Fig. 1).

Out of 65 studies, 26 studies did not mention the demographic area for the study of the population. The remaining studies included it, where 3 studies were conducted on the rural population, 25 studies on the urban population, and 11 studies were conducted on both rural and urban population. More than half of the studies were hospital based (35 out of 65) and rest of them were community based. Socio economic status for the study population was not mentioned in majority of the studies (42 out of 65). For socio economic groups of the population, 5 studies were conducted on lower economic groups and a single study was conducted on the upper and middle-income groups of the population. The rest

of them were conducted on a mixed population which represents the lower, middle and upper economic groups of the population. Maximum number of study designs were cross sectional (55 out of 65) and the rest of them were either case control or randomized control trials. Several kinds of measurement methods were used to determine vitamin D status like ELISA (Enzyme linked immunosorbent assay) RIA (Radioimmunoassay), Chemiluminescent Immunoassay (CLIA), Chemiluminescence micro particle Immunoassay (CLMA), HPLC (High performance liquid chromatography), Electro chemiluminescent immunoassay etc. Among these RIA and ELISA were mostly used (33 out of 65). Only four studies did not mention the method of vitamin D estimation [28–31]. A Summary outlining the characteristics of selected articles is presented in (Table 1).

The total population size of the studies finally selected was 44,717; which included both men and women. Participants were 18 years or above for maximum number of the studies. However, seven studies included adult

participants whose age range started from below 18 years [30, 47, 74, 75, 77, 79, 86].

Prevalence of vitamin D deficiency and average level of vitamin D was mentioned in all studies. Prevalence of vitamin D deficiency ranged from 17 to 99% and the average vitamin D level ranged from 4.7 ng/mL to 32 ng/mL. The overall pooled prevalence of vitamin D deficiency was 68% [95% CI: 64 to 72%] and the weighted mean level and weighted standard deviation (weighted SD) of vitamin D was 19.15 ng/mL and 11.59 ng/mL respectively.

There was a significant amount of heterogeneity in the prevalence of vitamin D deficiency ( $I^2 = 98.46\%$ ;  $p = 0.00$ ). Forest plot shows overall prevalence of vitamin D deficiency (Fig. 2).

Approximately 95% (62 out of 65) of our selected studies were conducted on the population of the Indian sub-continent (Bangladesh, India and Pakistan). Bar diagram (Additional file; Figure: A1) showed that weighted mean level of vitamin D was less than 20 ng/mL for this region.

**Table 1** Characteristics of selected study articles

Authors	Year	Country	Study area (urban or rural)	Study design	Age	Gender	Socio economic status	Vitamin D estimation method	Sample size (N)	Average level of vitamin D (ng /mL)	Standard deviation (S.D)

### Analysis according to country

The study encompassed 5 out of 8 SA countries which included Bangladesh, India, Pakistan Nepal and Sri Lanka.

No studies were found from Bhutan, Afghanistan and Maldives regarding vitamin D status. A forest plot displays country wise prevalence of vitamin D deficiency (Fig. 3).

**Fig. 2** Forest plot represent overall pooled prevalence of vitamin D deficiency among South Asian adults Each horizontal line of the forest plot represents an individual study and the box plotted as prevalence for that study. Diamond at the bottom represent overall prevalence when all the individual studies are combined together and averaged. The horizontal points of the diamond represent the limit of 95% confidence interval

Fig. 3 (See legend on next page.)

(See figure on previous page.)

**Fig. 3** Forest plot shows country-wise prevalence of vitamin D deficiency among South Asian adults. In this forest plot all the diamonds except the last one represents pooled prevalence in accordance with country; Sri Lanka (first), Nepal (second), Bangladesh (third), Pakistan (fourth) and India (fifth). Each horizontal line of the forest plot represents an individual study and the box plotted as prevalence for that study. The horizontal points of the diamond represent the limit of 95% confidence interval

### India

We found 39 studies from India which consisted of 38,672 participants. Mostly, these were cross sectional studies, which were either hospital or community based. Only four of these studies were case control and two were randomized control trial [32–70].

Out of 39 studies, 17 studies were conducted among urban populations, 3 studies on the rural population and 6 studies were conducted on population from both rural and urban areas. The remaining 13 studies did not mention demographic areas for the study population. The majority of the studies did not mention socio-economic status for the study population. The weighted mean level of vitamin D for study participants was 19.34 ng/mL (weighted SD 12.08 ng/mL) [Mean vitamin D level ranged from 4.7 ng/mL to 30.6 ng/mL]. Random effect meta-analysis showed that the weighted pooled prevalence of vitamin D deficiency was 67% [95% CI: 61 to 73%]. This finding indicated a high degree of heterogeneity among the population. ( $I^2 = 98.76\%$ ;  $p = 0.00$ ).

### Bangladesh

We found 5 studies from Bangladesh which consisted of 695 participants. These were either cross sectional or case control studies, being hospital or community based. Out of 5 studies, 2 studies were conducted among urban populations and the other 3 studies were on both rural and urban populations in Bangladesh. Most of the study participants belong to the lower socioeconomic class [71–75]. The weighted mean level of vitamin D for study participants was 16.14296 ng/mL (weighted SD 4.83 ng/mL) [Mean vitamin D level ranged from 12.3 ng/mL to 18.6 ng/mL] and random effect meta-analysis showed that the weighted pooled prevalence of vitamin D deficiency was 67% [95% CI: 50 to 83%]. A significant amount of heterogeneity was present ( $I^2 = 95.53\%$ ;  $p = 0.00$ ).

### Pakistan

We found 18 studies from Pakistan which consisted of 4354 participants. Study setting was either hospital based or community based and study design was cross sectional for most of the studies. Most of the studies did not mention demographic areas (urban/rural) for study population, 4 studies were conducted among urban populations and two studies included both rural and urban populations. Socio economic status for study participants was not mentioned in most of the studies, 8

studies were conducted on both lower and upper socio-economic groups of population and only one study was conducted on lower class population [28–31, 76–89]. The weighted mean level of vitamin D for study participants was 17.93 ng/mL (weighted SD 8.24 ng/mL) [Mean vitamin D level ranged from 8.44 ng/mL to 32 ng/mL] and random effect meta-analysis showed that the weighted pooled prevalence of vitamin D deficiency was 73% [95% CI: 63 to 83%] with high degree of heterogeneity ( $I^2 = 98.20\%$ ;  $p = 0.00$ ).

### Sri Lanka

We found only one study from Sri Lanka which was a community based cross-sectional study. Socioeconomic status was not mentioned. There were 196 participants and among them 47.95% were vitamin D deficient with mean vitamin D level of 21.68 ng/mL [90].

### Nepal

We found 2 studies from Nepal consisting of 800 participants together. Out of 2 studies, one study mentioned demographic area for study population but socioeconomic status was not mentioned for any of these studies [91, 92]. Study setting was either hospital based or community based and study design was cross sectional. Random effect meta-analysis showed that 57% [95% CI: 53 to 60%] of participants were vitamin D deficient with 19 ng/mL mean vitamin D level.

### Analysis according to gender

Out of 65 studies, 25 studies were conducted on adult females and 6 studies were conducted on adult males. Rest of the studies included both male and female adults as their participants. Gender-wise Forest plot is available in Fig. 4.

### Studies including participants from both gender

We found 35 studies which included participants from both gender (male and female). Among these studies, 20 studies were conducted on Indians, 12 studies on Pakistanis and a single study on Bangladeshi, Nepali and Sri Lankan adult. These studies comprised of 39,566 participants together and random effect meta-analysis showed that 65% [95% CI: 59 to 71%] of them were vitamin D deficient with a high degree of heterogeneity ( $I^2 = 98.89\%$ ;  $p = 0.00$ ). Average vitamin D level of study participants ranged from 7 to 32 ng/mL [Weighted mean 19.54 ng/mL and weighted SD 12.06 ng/mL].

### Meta-analysis of the Prevalence of Vitamin-D Deficiency (stratified according to the gender)

**Fig. 4** Forest plot shows gender wise prevalence of vitamin D deficiency among South Asian adult population. Each horizontal line of the forest plot represents an individual study and the box plotted as prevalence for that study. In this forest plot all the diamonds except the last one represents pooled prevalence in accordance with gender; studies which represent prevalence from both gender (first), female (second) and male (third). The horizontal points of the diamond represent the limit of 95% confidence interval

### Studies including only female adults

We found 25 studies which included only female adults as participants. Among these studies, 15 was conducted on Indians, 5 on Pakistanis, 4 on Bangladeshis and only one study on Nepali adult females. Together, these studies consisted of 4112 participants and random effect meta-analysis showed that 76% [95% CI: 68 to 82%] of study participants were vitamin D deficient with high number of heterogeneity ( $I^2 = 96.20\%$ ;  $p = 0.00$ ). The weighted mean vitamin D level of study participants was 14.68 ng/mL (weighted SD 7.86 ng/mL).

### Studies including only male adults

We found five studies which included only adult males as participants and all of these studies were conducted on Indian males. These studies comprised of 1039 participants and random effect meta-analysis showed that 51% [95% CI: 33 to 71%] of study participants were vitamin D deficient with high number of heterogeneity ( $I^2 = 97.68\%$ ;  $p = 0.00$ ). Weighted mean vitamin D level of study participants was 22.13 ng/mL (weighted SD 7.39 ng/mL).

A bar diagram shows weighted mean level of vitamin D among SA male and female (Additional file; Fig. A2).

### Analysis according to time

We segregated our selected studies into two groups; (1) studies conducted between 2001 and 2010, and (2) those conducted between 2011 and 2019. We found that most of the studies (48 out of 65) were conducted in the last decade (2011–2019). Random effect meta-analysis showed that prevalence of vitamin D deficiency was higher in 2001–2010 (73%; 95% CI: 64–80%) in comparison with 2011–2019 (66%; 95% CI: 61–72%). However, high degree of heterogeneity was observed in both time frame ( $I^2$  value of 96.83 and 98.66% for the two decades respectively;  $p = 0.00$ ). Forest plot for this comparison is available in Fig. 5.

### Quality assessment

Risk of bias score was calculated for each of the studies (Additional file: Table A2) following the method described by Hoy et al. in the year 2012 [23]. Studies that scored between 0 and 3 can be considered as having low risk of bias, and studies that scored 4–6 are moderate risk, and studies with scores of 7–9 can be considered as having high risk of bias. Among the 65 studies we selected; no study was found to contain a high risk of bias. Twenty-two studies showed low risk of bias, while the rest had a moderate risk of bias.

### Publication bias

The funnel plot for the prevalence of vitamin D deficiency is presented in the Additional file which indicated

the existence of asymmetry and publication bias (Additional file; Fig. A3). The Eggers test was found to be statistically insignificant which suggested no small study effects ( $p = 0.921$ ) among the studies.

In this systematic review and meta-analysis, we calculated the overall pooled prevalence of vitamin D deficiency among SA adults. We also showed country-wise and gender-wise prevalence of vitamin D deficiency in our sub-group analyses. Our findings also indicated that most of the studies were conducted on the Indian population. However, we did not find any studies regarding the vitamin D prevalence in Afghanistan, Maldives and Bhutan.

### Discussion

This study reveals that 68% [95% CI: 64 to 72%] of the SA adults are affected with vitamin D deficiency (Fig. 2). Comparison of this deficiency to the other parts of the world implies that this problem might be worse in SA compared to Southeast Asia (where the prevalence of vitamin D deficiency was found to vary from 6 to 70%) and Europe (around 40%) [93, 94]. We hypothesize that this high prevalence of vitamin D deficiency could be linked to the high prevalence of many health issues in this region. Indeed, this hypothesis is supported by some literature that several communicable and non-communicable diseases are rising in SA [16–18, 95, 96].

While high vitamin D deficiency in SA was the highlight of this study, we also found high degree of heterogeneity in the overall results ( $I^2 = 98.46\%$ ) (Fig. 2). We assume that geographical location and gender might act as a confounding variable for such a large-scale heterogeneity.

Country-wise comparison showed that Sri Lanka had the lowest percentage (48%) of prevalence, while Pakistan had the highest (73%). Compared to the Pakistani population, Bangladeshi and Indian population had a lower prevalence (67%). It is hypothesized that variability in the degree of sunlight exposure due to difference in geographical locations could be a probable reason for this [11, 97].

The people living in the tropical regions are exposed to more sunlight throughout the year as compared to those who live in subtropical regions. Vitamin D is synthesized naturally in the human body when UV-B from sunlight penetrates our skin and initiates the physiological processes of vitamin D synthesis [1, 3]. Pakistan is located in a sub-tropical region where sunlight availability is relatively low [98]. However, Bangladesh and India both share tropical and subtropical regions in their national map. High prevalence of vitamin D deficiency was also observed in other countries like Iran (56%) and China (70%) which share similar kinds of geographical location on their national maps [99, 100]. This

Fig. 5 (See legend on next page.)

(See figure on previous page.)

**Fig. 5** Forest plot shows prevalence of vitamin D deficiency in accordance with time among south Asian adult population. Each horizontal line of the forest plot represents an individual study and the box plotted as prevalence for that study. In this forest plot all the diamonds except the last one represents pooled prevalence in accordance with time; studies which conducted between 2001 and 2010 (first) and 2011–2020 (second). The horizontal points of the diamond represent the limit of 95% confidence interval

hypothesis can be further bolstered by the fact that the adults from Sri Lanka (a tropical country) showed the lowest prevalence of vitamin D deficiency among all the SA countries considered in this study.

Gender-wise comparison in our study reveals that females could be affected with vitamin D deficiency more than the males in SA; 76% for females (95% CI: 68 to 82%) as opposed to 51% for males (95% CI: 33 to 71%) (Fig. 4). We hypothesize that this might be related to a cultural aspect of this region; as lesser number of SA women spend their time outdoors which effectively limits their exposure to direct sunlight. In 2020, the World Bank reported that in SA the female labor force participation rate is around 24%, whereas male labor force participation rate is 80% [101]. Besides longer indoor time, clothing practice of women in the SA region could also be another cultural factor that could partially explain higher degree of vitamin-D deficiency among the females. The use of burqas (traditional full-body covering), hijab (Muslim wearing that covers the upper part of the body) and other non-religious body-coverings (traditional clothes) block direct sunlight exposure. These types of clothing practices are very common in many states of India, Pakistan and Bangladesh. A recent media report also suggests that these practices have increased exponentially in this region over the past three decades [102].

This hypothesis on the effects of clothing and staying indoor can be further supported by similar trends being observed in case of the women in the Middle East. World Bank reported in 2020 that female labor participation is around 20% in Middle Eastern countries [103]. More than 60% of Middle Eastern people prefer burqa as appropriate dress for Saudi Arabian women [104]. On top of that, a study report showed that 60% of women from Saudi Arabia living in Riyadh city had vitamin D deficiency [105].

Besides geography, gender, and clothing practices, a number of other factors (such as skin color) have also been reported in literature which can further explain the high heterogeneity that was observed in this study [1–3].

In this regard, in our study, we found that the Nepalese population had lower prevalence of vitamin D deficiency (57% [95% CI: 53 to 60%]) compared to the other countries from the Indian sub-continent (India, Pakistan, and Bangladesh) (Fig. 3). According to the Fitzpatrick scale, most of the Nepalese have lighter skin in comparison to population of the sub-continent, who tend to

have a darker skin complexion [106]. Though Nepal is located in a subtropical region [98], because of skin color, Nepalese might need less sunlight exposure in comparison to sub-tropical people for the production of similar level of vitamin D. Therefore, the variation of skin complexion could be a potential determinant of the observed variability of vitamin D deficiency among the SA countries.

High prevalence of vitamin D deficiency and low vitamin D status might act as a factor for the rise of these communicable and non-communicable diseases in this region. However, a recent study found that vitamin D deficiency is also associated with cytokine storm (dramatic immune system over reaction) which causes COVID 19 patients more vulnerable [107]. So, policy makers in this region need to take into account the high prevalence of vitamin D deficiency as well as the heterogeneity that has been identified in this study.

While this study highlights a critical health issue, it has few limitations well. Most of the studies that matched our selection criteria (59 out of 65) did not mention the socioeconomic conditions (e.g., income status and urban vs. rural difference). So, we could not test the effects of these factors in this study. Furthermore, we did not find any study from Bhutan, Maldives and Afghanistan. Only one study from Sri Lanka matched our inclusion criteria and two from Nepal. As such, because of insufficient data, we could not find the weighted mean level of vitamin D for these two countries. Another limitation is that a range of different methods were used in different studies to assay vitamin D in the serum. This might have introduced an assay bias to our findings. However, this limitation is inherent for all similar studies and was indeed unavoidable.

The high prevalence of vitamin D deficiency among SA adults is a public health challenge that should be addressed as an emergency, some even argue whether this should be treated as an ongoing pandemic [94]. Therefore, effectiveness of the mitigation strategies would be a critical public health challenge for the governments of SA. However, our search did not reveal any national level nutritional guidelines or policies addressing vitamin D deficiency in SA, except in India [108]. While existing guidelines and policies [108, 109] can be used as reference for the SA countries, we argue that the socio-cultural aspects of the individual countries (e.g., clothing practice, skin complexion, and economic status) also need to be taken into consideration. People, especially

the women, who practice heavy clothing and those who spend more time indoors can be encouraged to check their serum level of vitamin D on a regular basis and take necessary supplements. For people without adequate sunlight exposure, it has been recommended that, an adult should take 800–1000 IU of vitamin D per day [3]. In addition, SA population in general and especially the women can be encouraged to spend more time to boost natural production of vitamin D synthesis in their body [3]. In this regard, negative attitude towards sunlight exposure can be a big challenge in SA. It has been reported that lack of knowledge about vitamin D and negative attitude towards sunlight exposure is prevalent among Indian and Pakistani students [110, 111]. This lack of knowledge and negative attitude could be a key reason behind staying away from sunlight which can contribute to reduce serum vitamin D level. Introducing mass campaigns about the relationship between sunlight exposure and vitamin D deficiency may be really effective. Moreover, active measures should be taken to increase the number of diagnostic tests for detecting the serum vitamin D level. To achieve this, increasing the number of test centers, reduce price for testing the serum level of vitamin D by providing subsidies can also be considered by the governments in SA region.

## Conclusions

To the best of our knowledge, this is the first systematic review and meta-analysis on the prevalence of vitamin D deficiency among SA adults. Our findings point out that nearly seven out of ten adults in this region are suffering with vitamin D deficiency, while high inter-country variation was revealed. The results have generated evidence that underscores urgency of prioritizing the mitigation strategies. While this systematic review focused on SA only, the knowledge and insight generated from this study are transferable to other regions and countries with comparable geographic and socio-cultural aspects.

## Publisher's Note

Springer Nature remains neutral with regard to jurisdictional claims in published maps and institutional affiliations.

**Ready to submit your research? Choose BMC and benefit from:**

- fast, convenient online submission
- thorough peer review by experienced researchers in your field
- rapid publication on acceptance
- support for research data, including large and complex data types
- gold Open Access which fosters wider collaboration and increased citations
- maximum visibility for your research: over 100M website views per year

**At BMC, research is always in progress.**
